

Bring Siri AI to Your App

App Intents • AppSchema • Siri AI

From speech to an action inside your app.

About Me

iOS developer • builder • community contributor

Ashish Kakkad

iOS SDE III @ Genuin

Building iOS SDK for a product.

I build Apple-platform experiences with a focus on Swift, SwiftUI and Objective-C.

Beyond development, I enjoy learning and sharing practical iOS knowledge with the community.

About Siri AI (Beta)

The shift: Siri can understand more than a fixed command

UNDERSTAND

Natural language

People can express what they want conversationally.

CONNECT

Your app

App Intents and structured app data give Siri something actionable.

ACT

The right experience

The system can hand the request to the capability your app exposes.

The developer opportunity: expose the right intent + data model.

App Intents + AppSchema

The building blocks Siri can reason about

AppIntent

Expose an action

AppEntity

Describe app data

AppEnum

Describe choices

AppSchema

Use a known domain

Think of AppSchema as a shared vocabulary for common app experiences.

- App Intents expose actions to Siri and other system experiences.
- App Entities model meaningful objects such as a Fruit, Order or Document.
- App Enums make supported choices explicit and predictable.
- AppSchema lets your app adopt a recognized system domain.
- The result is structured context instead of a collection of ad-hoc phrases.

App Schema Domains

Schemas are organized around recognizable domains

Audio

Play, pause, or control audio

Calendar

Create and manage events

Camera

Capture photos or video

Clock

Timers, alarms, and clocks

Mail

Compose and manage email

Maps

Places, directions, and maps

Messages

Send and manage messages

Notes

Create and manage notes

Phone

Calls and phone actions

Photos

Search and work with photos

Reminders

Create and manage reminders

Search

Search content in your app

The domain tells the system what your intent means. [Reference Documentation](#)

searchInApp

The schema we'll use in today's demo

`.system.searchInApp`

User says...

"Find Banana in my app"

Siri understands the request

Search intent receives criteria

01

Intent

Expose the search capability

02

Criteria

Receive the search string

03

Results

Open the matching content

That's the bridge from Siri → App Intent → your in-app search.

Let's Look at the Demo

One request. One intent. One result.

Demo focus: searchInApp + AppEntity + row-level navigation

Thank You

Let's keep learning and sharing with the community.
